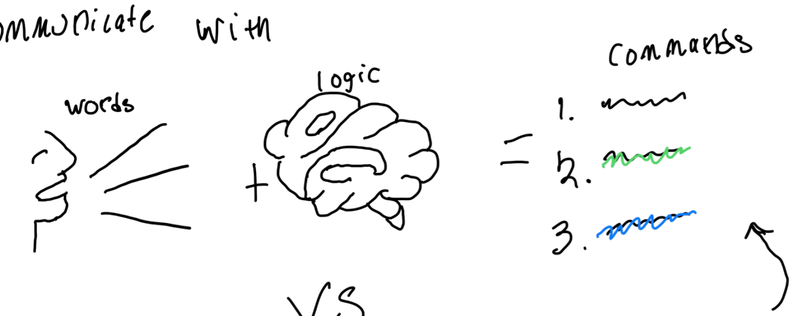
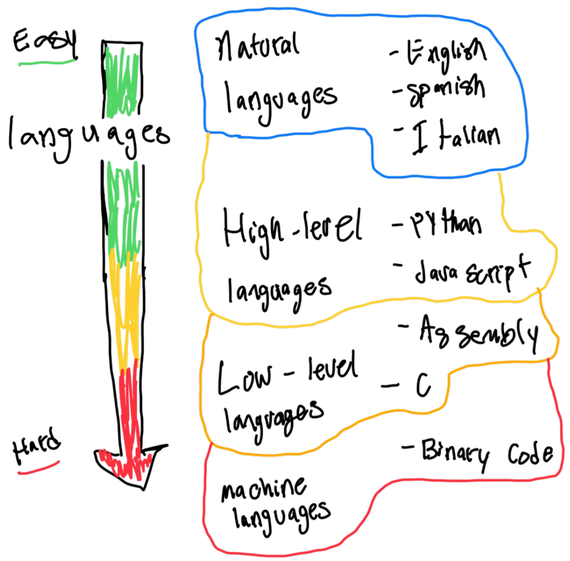
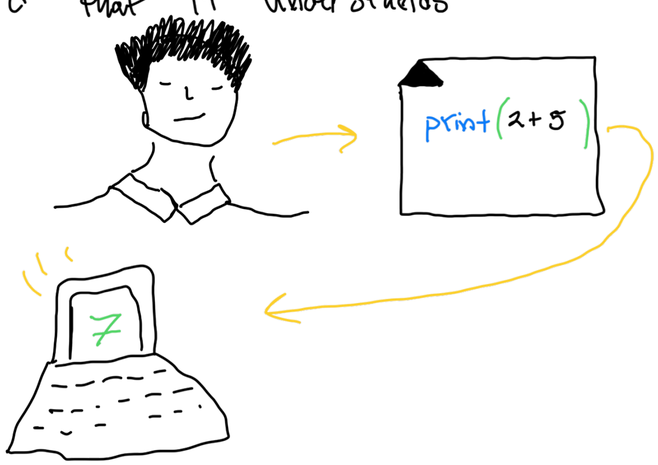
Python is a programming language

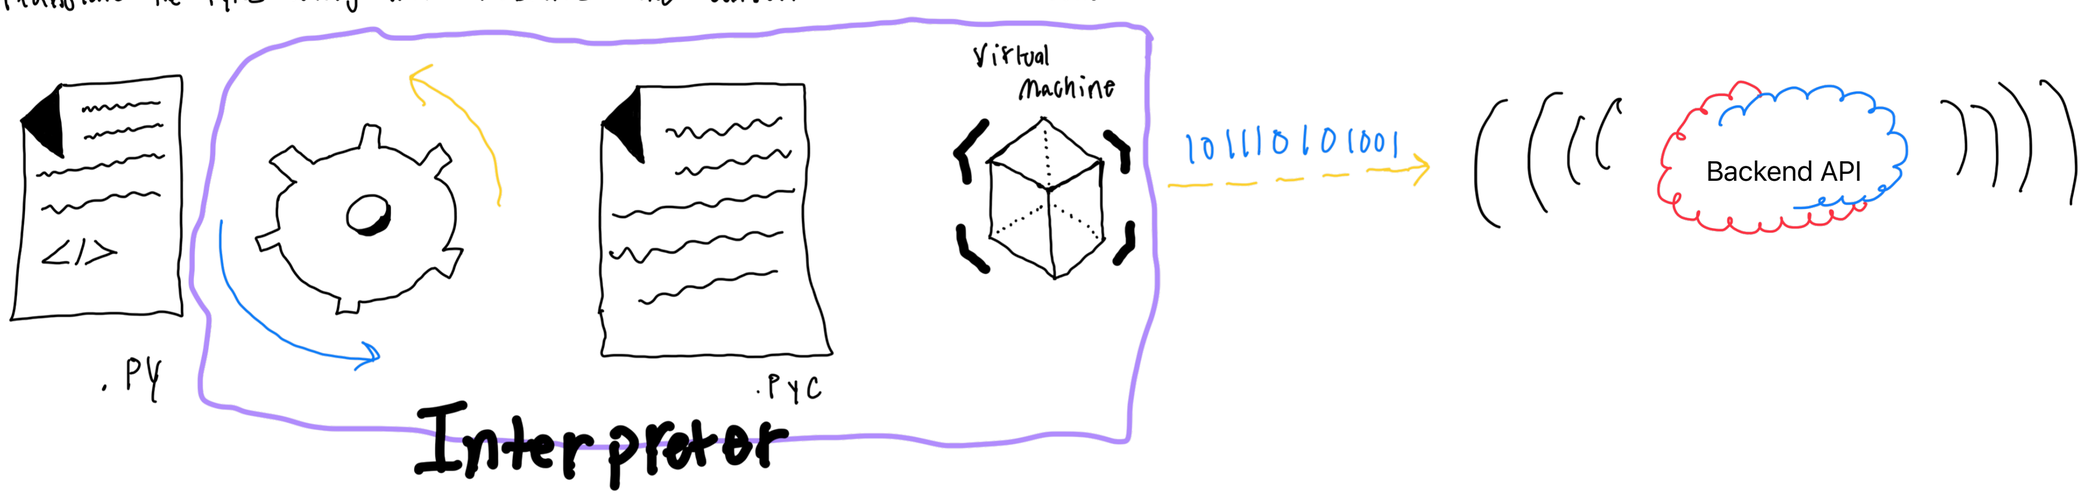
- A formal set of instructions, commands, and sytactical rules used to communicate with a computer to perform a specific task
- Serves as a medium between human logic and machine execution.



- We have to give the machine a command that it understands







- Python takes source code (which is high level), and compile to Byte code then gets passed to a VM. The virtual machine take the low-level Bytes and translate the Bytes along with Libraries and convert to machine code.
